## Background

The standard local therapy for breast cancer is surgery. **Postoperative seroma formation** is one of the most common and **serious complications after breast surgery** for primary breast cancer, especially in patients undergoing **mastectomy with or without implant-based breast reconstruction**. Seromas may lead to infections and wound dehiscence, which can **result in loss of reconstruction and poor cosmetic outcome**. To date, the **cause of seroma development** has **not yet been clarified.**

## Trial Design

The main objective of the **multicenter, minimal interventional SerMa study** is to **identify patients with an increased risk of developing seromas** based on **immunological or inflammatory markers** in blood and seroma fluid in a planned cohort of 2200 subjects. The study is designed as **international, prospective cohort study** in cooperation with the **EUBREAST Network** (European Breast Cancer Research Association of Surgical Trialists). Participating study groups are AGO-B, AWOgyn and OPBC. Patients with **primary breast cancer or ductal carcinoma in situ (DCIS)** planned for mastectomy with or without reconstruction can participate in this study (study group 1 and 2), a neoadjuvant treatment is possible. Study group 3 includes **patients at high risk for breast cancer** planned for **risk-reducing skin-sparing mastectomy and implant-based reconstruction**. Study group 4 includes **healthy women with implant insertion exclusively for cosmetic reasons**. Currently, **the logistics phase with 50 patients has been completed**, which was carried out to optimize the preservation of blood samples and seroma fluid.

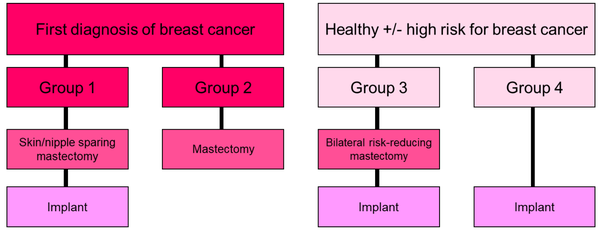

**Figure 1.** Overview of the four study groups

**Table 1.** Inclusion and exclusion criteria

| Study Group 1 and 2 | Study Group 3 and 4 |
|---|---|
| **Inclusion Criteria:** | |
| - Written informed consent<br>- Age ≥ 18 years<br>- DCIS (Tis) or all stages of invasive breast cancer (T1-T4, N0 or N+, M0) including all histopathological and biological subtypes (defined by ER/PR/HER2 status)<br>- Breast Surgery planned including ablative procedure or skin-sparing mastectomy with implant insertion (+/- Mesh/ADM) | - Written informed consent<br>- Age ≥ 18 years<br>- Surgical procedure planned with implant insertion (+/- Mesh/ADM) with or without subcutaneous mastectomy |
| **Exclusion Criteria** | |
| - Age <18 Jahre<br>- Male sex<br>- Breast cancer patients planned for breast conserving therapy<br>- Recurrent breast cancer<br>- History of breast surgery<br>- Diagnosis of LCIS only<br>- Pregnancy at time of diagnosis<br>- Patients with a known immunodeficiency<br>- History of cancer (any kind) | - Age <18 years<br>- Male sex<br>- History of breast surgery<br>- Pregnancy at time of surgery<br>- Patients with a known immunodeficiency<br>- History of cancer (any kind) |

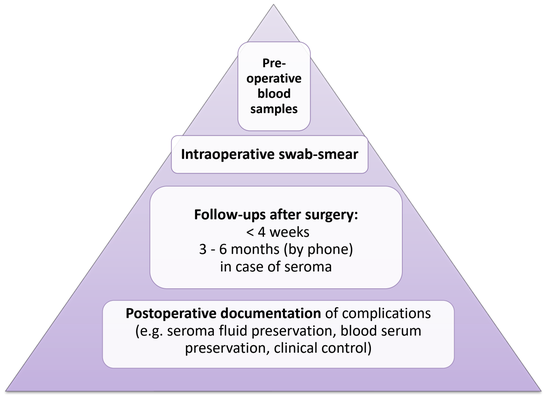

**Figure 2.** Study procedures

## Target accrual

2200 participants in total.

**Figure 3a**. Wound Dehiscence after Implant Based Reconstruction and seroma formation

**Figure 3b**. Seroma after bilateral mastectomy

## Current status of the study

Following the current finalization of the logistics phase the study **is open for recruitment**. The study is currently **expanding worldwide.**

## Primary endpoint

**The hypothesis** to be tested is: seromas after mastectomy arise **from immunological and proinflammatory processes** leading to **the possible identification of a patient group with an elevated risk of developing a seroma.** It is planned to examine the groups with and without postoperative seroma formation exploratory **regarding immunological markers in blood samples** (all patients) as well as **in seroma fluid** (if occurred). In addition, **local microbiome analyses**, as well as **tumor analyses** with focus on microenvironment will be performed to **differentiate possible carcinoma-specific immunological processes**.

## Secondary endpoints

In order to answer the question of whether differences in seroma formation are **caused by locally driven or systemic immunological or cancer-related factors**, groups with and without postoperative seroma formation will be further examined in subgroups.
